ECE 356 Winter 2018 1/26

### Deadlock

You should recall from learning about concurrency what deadlock is about, and therefore a brief review only is in order.

Those in need of a refresher are advised to take a look through previous courses' material to get caught up.

Others may find this to be review material, but it does deviate in some significant ways from the discussion of deadlocked processes.

ECE 356 Winter 2018 2 / 26

### Deadlock

We have already introduced the subject of deadlock and gave an informal definition as all transactions being "stuck" (unable to proceed).

A more formal definition: "the *permanent* blocking of a set of transactions that either compete for system resources or communicate with each other".

There is emphasis on permanent.

It may be possible for all transactions to be stuck temporarily, because one is waiting for some event (e.g., a read from disk).

ECE 356 Winter 2018 3/26

### **Conditions for Deadlock**

Remember, there are four condition necessary for a deadlock to take place:

- Mutual Exclusion
- Hold-and-Wait
- No Preemption
- 4 Circular-Wait

ECE 356 Winter 2018 4/26

#### Don't Handle It

We could choose not to handle deadlock.

This option is certainly convenient for database system designers!

While it is tempting and easy to just define a problem as being nothing we need to deal with, that's unrealistic in reality.

If two transactions get deadlocked, the user may simply see no progress and just feel bad about it.

ECE 356 Winter 2018 5/26

#### **Deadlock Prevention**

The first three conditions for deadlock (mutual exclusion, hold and wait, and no preemption) are all necessary for deadlock to be possible.

If we eliminate one of these three pillars, deadlock is not possible and it is prevented from happening.

If we prevent the circular wait from occurring, we are still in a world where deadlock can occur.

We cleverly avoid it taking place based on how we allow locks to occur.

ECE 356 Winter 2018 6/26

#### **Mutual Exclusion**

This pillar cannot, generally speaking, be disallowed.

The purpose of mutual exclusion is to prevent errors like inconsistent state or crashes.

Getting rid of mutual exclusion to rule out the possibility of deadlock is a cure that is worse than the disease.

It is therefore not acceptable as a solution.

ECE 356 Winter 2018 7/26

#### **Hold and Wait**

To prevent the hold-and-wait condition, we must guarantee that when a transaction requests a resource, it does not have any other resource.

One plausible solution is that the transaction must request all resources at the beginning of the program.

So if the transaction is going to need resources  $R_1$ ,  $R_2$ , and  $R_3$  at some point in the program:

All three must be requested right at the beginning and held throughout the transaction.

No further resources may be requested at any time during execution

ECE 356 Winter 2018 8 / 26

### No Preemption

If we violate this condition, it means that we do have preemption: forcible removal of resources from a transaction.

In the database context, if we have to preempt a transaction, it means the transaction in question is rolled back and then restarted.

To work out an ordering, transactions are assigned a timestamp.

If a transaction is rolled back, its timestamp remains the same

ECE 356 Winter 2018 9/26

## Or, Preemption

There are two approaches for what happens if we need to do pre-emption:

The first is called wait-die.

If a transaction  $T_i$  requests an item held by  $T_j$ , then the timestamps of these two transactions are compared.

 $T_i$  will be allowed to wait if it is older (i.e. its timestamp is a smaller number) than  $T_i$ , otherwise it "dies" (is rolled back).

ECE 356 Winter 2018 10 / 26

## Or, Preemption

The second is wound-wait.

If a transaction  $T_i$  requests an item held by  $T_j$ , then the timestamps of these two transactions are compared.

If  $T_i$  is the younger transaction (its timestamp is larger), then  $T_i$  can wait.

Otherwise,  $T_i$  is "wounded" by  $T_i$  and  $T_j$  is rolled back.

ECE 356 Winter 2018 11/26

So, in case of a conflict, one of the two transactions is going to be rolled back.

And it is always the younger one.

In either approach there may be unnecessary rollbacks...

ECE 356 Winter 2018 12/26

#### Timeout

Instead we could also have locks that have timeouts.

When a lock is requested there is a defined maximum time the transaction is willing to wait.

If that time limit is reached, the transaction rolls back automatically and begins again.

The obvious difficulty lies in choosing the length of time that the transactions will wait.

ECE 356 Winter 2018 13/26

### Circular Wait

We have already discussed the idea of using two phase locking to put an ordering on the locks and we need not repeat that yet again.

ECE 356 Winter 2018 14/26

### **Deadlock Detection**

A quick review of the graph algorithm follows, then.

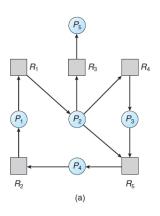

If resources have only a single instance, we may reduce the graph to a simplified version called the wait-for graph.

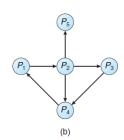

This removes the resource boxes from the diagram and indicates that a process  $P_i$  is waiting for process  $P_i$  rather than for a resource  $R_k$  that is held by  $P_i$ .

An edge  $P_i \to P_j$  exists in the wait-for graph if and only if the resource allocation graph has a request  $P_i \to R_k$  and an assignment edge  $R_k \to P_j$ .

ECE 356 Winter 2018 15 / 26

# **Deadlock Detection**

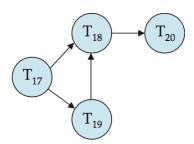

ECE 356 Winter 2018 16/26

### **Database Deadlock Detection**

Because locks are unique then there is no need to use the resource allocation graph and we can always use the simplified wait-for graph for transactions:

ECE 356 Winter 2018 17/26

# **Deadlock Detection is Expensive**

Cycle detection algorithms tend to have runtime characteristics of  $\Theta(n^2)$  where n is the number of nodes in the graph.

How often should the deadlock detection algorithm be run?

ECE 356 Winter 2018 18/26

# **Deadlock Recovery**

On the subject of what transaction to select as a victim we already identified the timestamp as one possible way to decide. Or:

- 1 How long the transaction has been executing.
- 2 How long is remaining in execution (see the estimates from the execution plan).
- 3 What resources the transaction has used.
- 4 Future resource requests, if known.
- 5 How many times, if any, the transaction has been selected as a victim (to prevent starvation).

ECE 356 Winter 2018 19 / 26

# Push the Ball Uphill

We chose a victim, now simply roll that transaction back!

That would be a total rollback: undo all the steps of the transaction and start from the beginning once again.

There exists, however, the ability to do a partial rollback.

ECE 356 Winter 2018 20 / 26

### Partial Rollback

The goal of the partial rollback is to rollback the transaction back only as much as is necessary to break the deadlock.

This is accomplished by maintaining the sequence of lock requests and grants.

By finding the lock(s) that are implicated in the deadlock, we can roll back a transaction to where it obtained the first of such locks.

ECE 356 Winter 2018 21/26

# **Lock Granularity**

Locks' extents constitute their granularity: that is, how much data is being protected by such a lock.

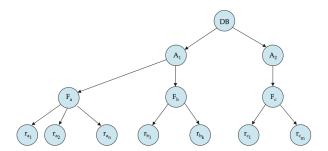

Coarse-grained locking is easier to implement, but it can significantly reduce opportunities for parallelism.

Fine-grained locking requires more careful design, increases locking overhead and is more prone to bugs (deadlock etc).

ECE 356 Winter 2018 22 / 26

# **Granularity Hierarchy**

In the database we could define multiple levels of granularity.

ECE 356 Winter 2018 23 / 26

#### **Intention Lock Modes**

A more efficient route is intention lock modes, which are put on the ancestors of a node before the node is locked.

These intention locks can be checked while traversing the tree. The following modes are possible:

- Shared (S)
- **Exclusive** (X)
- Intention Shared (IS)
- Intention Exclusive (IX)
- Shared Intention Exclusive (SIX)

ECE 356 Winter 2018 24/26

#### **Intention Lock Rules**

Then a transaction must follow the six rules below:

- All attempts to lock must observe the table (below) as to whether they are permitted to proceed (or wait).
- The transaction must lock the root of the tree first (in any mode, but it must pick one).
- A node n can be locked in S or IS mode only if the parent of n is locked in either IX or IS mode.
- 4 A node *n* can be locked in **X**, **SIX**, or **IX** mode only if the parent of *n* is locked in either **IX** or **SIX** mode.
- A node *n* may only be locked if the transaction has not previously unlocked any nodes.
- **6** A node *n* may only be unlocked if none of the children of *n* are locked by this transaction.

Locks must be acquired in a top-down manner and then released in a bottom-up manner.

ECE 356 Winter 2018 25 / 26

# Lock Compatibility Matrix

Compatibility	IS	IX	S	SIX	X
IS	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	×
IX	<b>√</b>	<b>√</b>	×	×	×
S	<b>√</b>	×	<b>√</b>	×	×
SIX	<b>√</b>	×	×	×	×
Х	×	×	×	×	×
